

Artificial Intelligence Overview

Artificial Intelligence (AI) enables computers to perform tasks that normally require human intelligence. Common applications include computer vision, natural language processing, speech recognition, and recommendation systems.

Machine Learning (ML) is a branch of AI where models learn patterns from data. Deep Learning uses neural networks with many layers for complex tasks.

Retrieval-Augmented Generation (RAG) enhances large language models by retrieving relevant information from external documents. The pipeline typically includes document loading, text splitting, embedding generation, vector database storage, retrieval, and answer generation.
